000			
Motivations			

- Real world networks (i.e. webgraphs, online social networks) are huge
- Even though there are distributed platforms for large scale graph processing still graph compression is beneficial:
 - Processing larger portion of graph per computer
 - Reducing the communication cost
- Ideally we like to be able to run different types of query on the compressed graph

Motivations

"Data mining = Compression" C. Faloutsos [Data mining for fun, Innovation Award talk, KDD10]

Background	Our Framework	Formalization	Experiments
Existing Approac	hes: Web graphs		

Boldi and Vigna [WWW04]

- Locality of webgraphs: A large percentage of links are intra-domain
- Sort by URL to improve locality of links
- Sort the list of out-links for each node
- Use ζ codes to encode the gaps between out-links
- This compress the webgraphs down to almost 2 bits per edge

Background	Our Framework	Formalization	Experiments
0000	000000	000000	00000
Existing approac	hes: Friendship net	works	

Chierichetti et. al. [KDD09]

- There is no natural ordering of vertices for friendship networks
- Instead of sorting by URL in the previous approach, use shingle ordering
- Shingle ordering tends to place nodes with similar out-links list close to each other (similar in the sense of Jaccard Coefficient)
- The compression rate is not nearly as good as webgraphs

Some Obse	rvations		
0000	000000	000000	00000
Background	Our Framework	Formalization	Experiments

Observation: The optimality of adjacency matrix representation

- Consider the class of random graph on *n* vertices where each possible edge is included in the graph with probability half
- Based on information theoretical lower bound, Any compression scheme on expectation uses at least n^2 bits
- Provably for this class of graphs adjacency matrix is the optimal schema
- Message: Roughly speaking for dense random graph adjacency matrix is the best option

Some Obse	wations		
	00000		
Background	Our Framework	Formalization	Experiments

Observation: The optimality of adjacency list representation:

- Consider the class of random graph on *n* vertexes, where:
 - Each vertex has only one outgoing edge
 - The destination of that edge is picked uniformly at random
- For this class of graphs any compression scheme on expectation uses at least $n \log n$ bits
- In this case provably adjacency list is the optimal schema
- Message: Roughly speaking for sparse random graph adjacency list is the best option

Background	Our Framework	Formalization	Experiments
	00000		
The Idea			

- It is well known that social networks are locally dense and globally sparse
- Question: Is it possible to combine the adjacency matrix and adjacency list effectively to get a compression schema?
- General Idea: For "local" edges use adjacency matrix and for "global" connections use pointers

Background	Our Framework	Formalization	Experiments
0000	○○0●00	000000	00000
The Idea			

- Let's consider a very simple case
- Assume a linear arrangement of nodes is given
- Notice that all the edges are "local" (i.e. every edge is connecting two nodes next to each other)

Background 0000	Our Framework	Formalization	Experiments 00000
The Idea			

- Let's consider a very simple case
- Assume a linear arrangement of nodes is given
- Notice that all the edges are "local" (i.e. every edge is connecting two nodes next to each other)

Background	Our Framework	Formalization	Experiments
	000000		
The Idea			

- Now we consider a more sophisticated case
- In this case there is no arrangement of vertices such that every edge is "local"
- Relaxation: A node can appear more than once

Background	Our Framework	Formalization	Experiments
	000000

Representation S	Schema		

- Representation schema is an array in which each cell consists of a pointer and two bits
- The index of the first appearance of a node is its ID
- We can extent the idea by using 2k bits for each position to encode the outlinks that are at most k positions away

Background	Our Framework	Formalization	Experiments
0000	000000	●00000	00000
S-distance			

• Given a sequence S of nodes of the graph, the S-distance between u and v, is the minimum norm-1 distance among all pairs of appearances of u and v

MP _k linearization	n		

• An MP_k linearization of graph G is a sequence S of vertices, such that for all $(u, v) \in E(G)$, S-dist $(u, v) \leq k$

Background	Our Framework	Formalization	Experiments
		00000	
MP_k linearization	n		

An MP_k linearization of graph G is a sequence S of vertices, such that for all (u, v) ∈ E(G), S-dist(u, v) ≤ k

MP _k linearization	n		

An MP_k linearization of graph G is a sequence S of vertices, such that for all (u, v) ∈ E(G), S-dist(u, v) ≤ k

Given MP_k linearization L of G, one can encode G using (2k + ⌈log|L|⌉) × |L| bits, where |L| is the length of L

Finding optimal	MP ₁ linearization		

Minimum MP₁ linearization

- Start from a node with odd degree, if there is no such a node, start from an arbitrary node with nonzero degree
- Choose an edge whose deletion does not disconnect the graph, unless there is no other choice
- Move across the edge and remove it
- Keep removing edges until getting to a node that does not have any remaining edge to choose
- If the graph is not empty go to step 1

Background	Our Framework	Formalization	Experiments
		000000	

- This algorithm partitions the edges to exactly $N_{odd}/2$ edge-disjoint paths,where N_{odd} is the number of vertices with odd degree (assuming $N_{odd} > 0$)
- The length of an optimal MP1 linearization is $|E| + N_{odd}/2$ ($N_{odd} > 0$)
- It can be implemented in O(|E|) time

Background	Our Framework	Formalization	Experiments
		000000	
Compression Ra	te [,] Unner Round		

Using MP_1 linearization to encode a graph G the bits/edge rate is at most

$$(1+rac{1}{ar{d}})\Big(\lceil \log_2(|V(G)|) + \log_2(ar{d}+1)
ceil + 1\Big)$$

while the in-neighbor and out-neighbor query processing time is

$$O\Big(\sum_{u\in N_{v}} deg(u) \log |V(G)|\Big)$$

The trivial encoding of the graph that answers both in-neighbor and out-neighbor queries uses $2 \log |V|$ bits/edge

Background	Our Framework	Formalization	Experiments
		00000	
Hardnore Doculto			

- How hard is it to compute an optimal MP₂ linearization?
 - We don't know, pretty hard I guess!
- Minimum MP_k linearization when k is part of the input is a generalization of Min-Bandwidth problem and therefore it is NP-hard
- Min-Bandwidth problem: Find an arrangement of vertices of the graph that minimize the maximum stretch of an edge

Background	Our Framework	Formalization	Experiments
0000	000000	000000	●○○○○
MP_{ν} linearization	tion: Heuristic		

- A greedy heuristic to compute MP_k linearization:
 - Start with a random node and add it to list
 - Find the node that has the most number of edges to the last k nodes in the list
 - Remove the edges between this node and the last k nodes in the list
 - Add the node to the list
 - Repeat until no edge is left
- The graph gets sparser and sparser while we are removing the edges
- We use a threshold to reduce the value of k in the process of linearization

Comparison

Comparison: The compression rate of the previous schema [KDD09] on LiveJournal dataset is 14.38 while it can only answer out-neighbor queries, our compression rate is 13.91 while our method can answer both in-neighbor and out-neighbor queries

Background	Our Framework	Formalization	Experiments
0000	000000	000000	000●0
Conclusions			

- We introduce a novel framework for representing graphs
- In its simplest settings, our framework comes with an upper bound on bits/edge rate
- Our method can efficiently answer more types of query and retain the comparable compression rate than the state-of-the-art methods
- Our framework reduces the problem of compressing a graph to an intuitive combinatorial problem

Background	

Future works

- Finding smarter algorithms for linearizing a graph
- Using other compression techniques on top of our framework
- Hardness result for MP_k linearization when k is fixed
