# Outline

- 1 Introduction
- 2 Proposed method
- 3 Related work
- 4 Evaluation
- 5 Conclusion

# Motivation

- While news is produced through traditional channels, a lot of content related to these news events is produced through social media
- People post messages to share a particular news article, to express an opinion about the ongoing events, or to add or refute information about the topic or the mentioned article.
- Displaying social responses near a news article for an enhanced reading experience.

# Motivation

- While news is produced through traditional channels, a lot of content related to these news events is produced through social media
- People post messages to share a particular news article, to express an opinion about the ongoing events, or to add or refute information about the topic or the mentioned article.
- Displaying social responses near a news article for an enhanced reading experience.

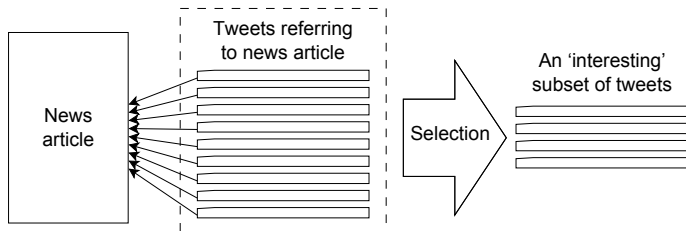

# Motivation

- People post messages to share a particular news article, to express an opinion about the ongoing events, or to add or refute information about the topic or the mentioned article.
- Displaying social responses near a news article for an enhanced reading experience.

# Situation

Given:

- a news article
- a set of tweets, responding to that news article

# Hypothesis

Our hypothesis is that an interesting subset consists of diverse, informative, opinionated and popular messages composed by users with authority.

# Problems

- There is a huge volume of tweets, but few actual distinct messages;
- Many tweets are repetitions of the title of the news article, having no additional information;
- Some of them have different content, but are nevertheless redundant;
- Yet, some people actually contribute novel facts or insightful remarks;

# Problems

- There is a huge volume of tweets, but few actual distinct messages;
- Many tweets are repetitions of the title of the news article, having no additional information;
- Some of them have different content, but are nevertheless redundant;
- Yet, some people actually contribute novel facts or insightful remarks;

## Problem statement

Given a news article and a set of related messages  $M$ , we seek a subset  $S$  of  $M$ , of size  $k$ , which are the most "interesting" to a typical reader in the context of the article

## Proposed solution

We computationally model the four message-level indicators using an utility function  $r$  and the set-level diversity indicator using a normalized entropy function  $H_0$ , combined into a common objective function  $g(S)$

## Objective function

The solution to the social message selection problem is to optimize this objective function:

$$S^* = \arg \max_{S \subset M, |S|=k} (g(S)) \quad (1)$$

$$g(S) = \lambda \sum_{m \in S} r(m) + (1 - \lambda) H_0(S) \quad (2)$$

We consider the properties of our objective function to find a fast approximation to the problem.

## Objective function

The solution to the social message selection problem is to optimize this objective function:

$$S^* = \arg \max_{S \subset M, |S|=k} (g(S)) \quad (1)$$

$$g(S) = \lambda \sum_{m \in S} r(m) + (1 - \lambda)H_0(S) \quad (2)$$

We consider the properties of our objective function to find a fast approximation to the problem.

## Objective function

To this end, we demonstrate that  $g(S)$  is a submodular set function, meaning that the difference of the value of the function that a single element addition makes decreases as the size of the input set increases.

## Objective function

- $r(S) = \sum_{m \in S} r(m)$  - submodular, since

$$\forall X, Y \subseteq \Omega, X \subseteq Y, \forall x \in \Omega \setminus Y : \quad (3)$$
$$f(X \cup \{x\}) - f(X) \geq f(Y \cup \{x\}) - f(Y)$$

- $H_0(S)$  - entropy is also known to be submodular
- A linear combination of submodular set functions is also submodular, which is why a greedy approach is at most  $1 - \frac{1}{e}$  times worse than the optimal set of examples.

## Objective function

- $r(S) = \sum_{m \in S} r(m)$  - submodular, since

$$\forall X, Y \subseteq \Omega, X \subseteq Y, \forall x \in \Omega \setminus Y : \quad (3)$$
$$f(X \cup \{x\}) - f(X) \geq f(Y \cup \{x\}) - f(Y)$$

- $H_0(S)$  - entropy is also known to be submodular
- A linear combination of submodular set functions is also submodular, which is why a greedy approach is at most  $1 - \frac{1}{e}$  times worse than the optimal set of examples.

## Objective function

- $r(S) = \sum_{m \in S} r(m)$  - submodular, since

$$\forall X, Y \subseteq \Omega, X \subseteq Y, \forall x \in \Omega \setminus Y : \quad (3)$$
$$f(X \cup \{x\}) - f(X) \geq f(Y \cup \{x\}) - f(Y)$$

- $H_0(S)$  - entropy is also known to be submodular
- A linear combination of submodular set functions is also submodular, which is why a greedy approach is at most  $1 - \frac{1}{e}$  times worse than the optimal set of examples.

## Objective function - scoring

- Let  $r$  be a function, modeled by  $\theta$ , that outputs a real value for a given tweet  $t$  :  $y_i = r(t_i|\Theta), y_i \in \mathbb{R}$
- We obtain  $\Theta$  by training a support vector regression model on individual tweet judgments:  $(\mathcal{T}, y_{gold})$

## Objective function - scoring

- Let  $r$  be a function, modeled by  $\theta$ , that outputs a real value for a given tweet  $t$  :  $y_i = r(t_i|\Theta), y_i \in \mathfrak{R}$
- We obtain  $\Theta$  by training a support vector regression model on individual tweet judgments:  $(\mathcal{T}, y_{gold})$

# Algorithm

---

## Algorithm 1: Greedy iterative sampling algorithm

---

**Input** : A collection of messages  $M$ , the sample size  $k$

**Output**: A sample set of messages  $S^*$

$S \leftarrow \{\arg \max_{m_i \in M}(r(m_i))\}$

**while**  $|S| < k$  **do**

$m^* \leftarrow \arg \max_{m_i \in M \setminus S}(g(S \cup \{m_i\}))$

$S \leftarrow S \cup \{m^*\}$

**end**

$S^* \leftarrow S$

---

# Features

Both components of  $g(S)$  have distinct features sets: features for  $r(S)$  are scoring features, while features for  $H_0(S)$  are selection features.

**Selection features:** n-grams, location, retweet, reply

**Scoring features:** average TF-IDF score, log-likelihood given a language model, length, me-information, question, quotation, quality, sentiment, intensity, controversy, retweet, reply, friends, followers, follower-friend ratio, number of retweets, tweet-retweet ratio, user is verified, user is spam, user authority, user topic authority

# Features

## Related work: Diversity-based sampling<sup>1</sup>

**Goal:** sample tweets with respect to the desired diversity level

**Method:** greedy approach that iteratively picks tweets that minimize the distortion of entropy of the current subset using a probabilistic model of tweets given their diversity using social, content and network features.

**Label:** diversity

## Related work: Social context summarization <sup>2</sup>

**Goal:** Joint summarization of news and tweets;

**Method:** based on conditional random fields that simultaneously addresses message and document summarization by modeling messages and sentences as connected 'wings' in a factor graph

**Label:** LR+, DWFG

---

<sup>2</sup>Zi Yang et al.: Social Context Summarization, SIGIR 2011

## Our contribution

- We focus on a comprehensive notion of interestingness instead of solely optimizing for message diversity;
- We detect and avoid redundancy between the content of messages by including a richer set of textual features;
- We model the importance of messages beyond their literal content by including features that capture the wider social, conversational and linguistic context;
- We provide a theoretic guarantee of the sample quality.

## Methods

## Scenario 1: individual message labeling

Given a news article and a set of messages, judge each tweet on  $\{-1, 0, +1\}$  on each of the following criteria:

- Informative:** the message brings new information to the news article and sample.
- Opinionated:** the message expresses a strong/controversial opinion or emotions.
- Interesting:** the message would serve as a good example of presenting the essence of the people's response to news.

Popularity and authority are computed mechanically.

## Scenario 1: individual message labeling

Given a news article and a set of messages, judge each tweet on  $\{-1, 0, +1\}$  on each of the following criteria:

- Informative:** the message brings new information to the news article and sample.
- Opinionated:** the message expresses a strong/controversial opinion or emotions.
- Interesting:** the message would serve as a good example of presenting the essence of the people's response to news.

Popularity and authority are computed mechanically.

# Dataset

**28,055 messages**, gathered from Twitter, referring to **45 news articles** annotated with **3 indicators** by **14 professional editors**.

## Individual message labeling - evaluation

We evaluate the individual message labeling modeling using  $F_1$  and ROUGE, a widely used metric in text summarization.

These scores measure how closely the output of a method on a single tweet is to the “ideal” output, i.e. those scored positively by the annotators.

## Individual message labeling - evaluation

We evaluate the individual message labeling modeling using  $F_1$  and ROUGE, a widely used metric in text summarization.

These scores measure how closely the output of a method on a single tweet is to the “ideal” output, i.e. those scored positively by the annotators.

# Individual message labeling

**Table :** Comparison of the tweet sets generated by the various methods in terms of their informativeness, opinionatedness and interestingness as measured by ROUGE-2 and  $F_1$  at  $k = 10$

	Informative		Opinionated		Interesting	
	R-2	$F_1$	R-2	$F_1$	R-2	$F_1$
DIVERSITY	0.178	0.050	0.270	0.108	0.280	0.109
DWFG	0.170	0.048	0.259	0.056	0.235	0.051
LR+	0.175	0.032	<b>0.355</b>	0.132	0.264	0.054
ENTROPY	<b>0.246*</b>	0.124*	0.345	0.184*	<b>0.357*</b>	0.216*
SVR	0.212*	<b>0.132*</b>	0.326	<b>0.217*</b>	0.336*	<b>0.239*</b>
SVR_ENTROPY	0.232*	0.123*	0.343	0.211*	0.346*	0.224*

## Decomposing interestingness of individual messages

We fitted a least-squares linear model to the indicators and obtained the following linear combination, supported by a coefficient of determination  $R^2$  of 0.38:

$$int = 0.60 \cdot inf + 0.29 \cdot opi + 0.03 \cdot pop + 0.10 \cdot aut \quad (4)$$

## Pairwise sample comparison

Given a news article and the associated tweets, we let evaluators choose between two message selections, generated by different approaches.

- Combining diversity and scoring?
- Comparison against baselines?

## Pairwise sample comparison

Given a news article and the associated tweets, we let evaluators choose between two message selections, generated by different approaches.

- **Combining diversity and scoring?**
- **Comparison against baselines?**

## Pairwise sample comparison

**Table :** Comparison of tweet selection methods based on annotator preference votes.

Method A	Method B	Votes A	Votes B	None	$p$ -value
<b>Combining entropy with scoring</b>					
SVR	SVR_ENTROPY	151	<b>194</b>	16	0.02
SVR	ENTROPY	<b>193</b>	155	9	0.04
ENTROPY	SVR_ENTROPY	114	<b>147</b>	13	0.04
<b>Comparison against baselines</b>					
DIVERSITY	SVR_ENTROPY	79	<b>158</b>	3	0.00
DWFG	SVR_ENTROPY	99	<b>149</b>	5	0.00
DWFG	DIVERSITY	<b>118</b>	94	10	0.10

## Distribution of preference reasons

Method A	Method B	inf.	opi.	aut.	pop.
SVR	SVR_ENTROPY	163	197	59	49
ENTROPY	SVR	139	226	43	54
ENTROPY	SVR_ENTROPY	160	125	24	13
DIVERSITY	SVR_ENTROPY	147	122	66	68
DIVERSITY	DWFG	166	109	66	50
DWFG	SVR_ENTROPY	146	134	85	68

# Conclusion

- We show that SVR\_ENTROPY, a near-optimal solution to the message selection optimization problem outperforms other baselines in a head-to-head comparison scenario.
- We show how various indicators affect interestingness: informativeness being most important, followed by opinionatedness and user authority.

# Conclusion

- We show that SVR\_ENTROPY, a near-optimal solution to the message selection optimization problem outperforms other baselines in a head-to-head comparison scenario.
- We show how various indicators affect interestingness: informativeness being most important, followed by opinionatedness and user authority.

# Conclusion

*Interestingness* of a message and a message set:

- For individual messages, *informativeness* is most important but simultaneously the most difficult to judge, followed by *opinionatedness* and *popularity*.
- *Message set interestingness* was tied most strongly to *opinionatedness* and then to *informativeness*.

## Future work

- Incorporating additional message- and author- level indicators
- Personalizing interestingness models
- Abstractive summarization
- Online sampling
